

# SRC-03: Registration Table Date Renewed Value

## Change Description:

Adding a date\_renewed field to the registration table. This would be a unix\_timestamp in the same format as the existing date\_registered field. This would track the latest certificate renewal, to ensure that the certificates are being cycled regularly and the device is constantly doing that on our schedule that we have planned.

## Change Level:

Feature, just a quick augmentation to the registration table.

## Change Type:

Addition, adding a field to a table

## Justification:

We have a date for when the device is first connected to the system. We have a value for how long the certificate is valid. It would be a smart idea to include the latest registration date so we can a.) see that the device is actually renewing its certificate and communicating with the server regularly, and b.) Be able to calculate the expiration date by adding the last registration date and the time to live value(already present). Showing the certificate expiration date is a nice piece of data to have and present to trail managers.

## Impact:

Minor technical impact, framework and functionality for doing such is already present in the backend, adding it is trivial. Updating the frontend to include the value and potentially the expiration date shouldn't be too challenging as well, as it would just be additional values for the device page
